

ADR-001: DevEx Golden Path Ecosystem

Status: Final · **Author:** Jorge Flores · **Date:** 2026-05-26

Decision. Build a polyglot Golden Path as two independently distributable packages — `devex-cli` (Python, `uv tool install`) and `@devex/framework` (TypeScript, `pnpm add`) — homologating the lifecycle across 10+ teams without putting the platform team in the critical path.

Context. Org scaling from a handful of teams to 10+. DORA metrics are not comparable across teams. SOC 2 audit is painful because each team owns CI/CD differently. The current platform team is a bottleneck for every CI/CD change.

1. Architecture overview

The full architecture diagram lives in the project [README](#).

Key properties. Two products with separate versioning, install commands, and consumers — coupled only by shared schemas (DORA event, Work ID regex, audit log) defined once in the monorepo and consumed by both. A single Git tag releases CLI + Framework atomically; cross-cutting changes are one PR. The `StackProfile` discriminated union (`python-lambda-api`, `go-lambda-api`, ...) is the only place a language is named — adding Go means one new profile plus stub implementations, **not** a framework fork. DORA and audit events use a standardized schema; the framework defines the contract, the org's existing pipelines define storage.

2. Homologation

Adoption is engineered, not requested.

Lever	Mechanism
Lower the cost	<code>devex init</code> scaffolds the entire Golden Path in one command (workflows, lint configs, hooks, branch protection) and auto-detects <code>repo-url</code> from <code>git remote</code> plus <code>service-name</code> from the working directory — zero required flags. Time-to-first-green-PR drops from days to under 10 minutes.
Self-enforce	Four checkpoints fire before the platform team is involved: (1) IDE lint/format/type-check on save; (2) pre-push hook calls <code>devex validate</code> plus optional <code>devex check</code> for test/lint; (3) generated PR pipeline re-runs validation, contract checks, and <code>cdk synth</code> with FinOps-tag enforcement; (4) branch protection blocks merges without required status checks. Checkpoint 4 requires a one-time org-level governance step — a GitHub Ruleset with required-status-checks list (or Terraform equivalent) keyed by a <code>devex-adopted</code> custom property that <code>devex init</code> sets on adoption. The platform team configures the ruleset once per org; consumer teams don't need admin scope. Until that one-time setup is done, the PR pipeline jobs are emitted but not enforced as required checks.
Migrate safely	<code>devex init --migrate</code> runs inspect-only by default for existing repos. <code>--apply</code> writes incremental PRs the team reviews. Eventual convergence, never big-bang. Reruns are idempotent (UNIX exit codes: <code>0</code> = ok or no-op, <code>1</code> = partial state, <code>2</code> = misuse).
Friction-free DX	Work IDs auto-inject into commit messages via <code>prepare-commit-msg</code> (developer never types <code>KAN-123:</code> again). Hooks bake the absolute <code>devex</code> path at install time so they survive Git's sanitized <code>PATH</code> . The pre-push hook is bypassable with <code>--no-verify</code> — the PR pipeline re-validates and cannot be bypassed.

Anti-patterns rejected: voluntary adoption (fails at scale), big-bang migration (kills trust), mandatory training (if the CLI needs a class, we've failed at DX), hook-as-moat (treat hooks as gifts to the developer; let branch protection be the moat).

3. Scalability — keeping the platform team out of the critical path

Three mechanisms make the platform team scale sub-linearly with team count.

- **Extension over modification.** Every Construct and workflow factory accepts override hooks (`smallTestsJob(profile).addStep(customStep)`, `props.lambdaOverrides`). Teams customize without forking. The `StackProfile` discriminated union with `assertNever` exhaustiveness means adding a language is additive, never invasive — the TypeScript compiler enumerates deterministically the call-sites the contributor must extend (`smallTestsJob`, `cdkSynthJob`, `contractValidationJob`; typically N≈3-5 hand-edits) plus one new profile file. A planned `devex add-language <name>` codemod reduces the edits to zero by scaffolding the stub at each call-site.
- **Inner-source.** Any team can PR the monorepo. The framework's own pipeline is the gate; review goes to a rotating maintainer (1 platform + 1 IC from consumer teams). Breaking changes require a 5-day RFC; additive changes don't.
- **Platform team's actual job:** maintain contracts, curate inner-source contributions, run the upgrade path (semver, deprecation). **Not:** write per-team CI/CD, debug per-team failures, gatekeep custom infra.

4. Shift-Left strategy

Defects detected where they are cheapest. Four layers, ordered left-to-right; each layer's bypass is re-caught at the next:

1. **IDE / Local** — lint, format, type-check on save, configured by `devex init` (no new tools, just enforced configs).
2. **Pre-push hook** — `devex validate` checks Work ID in branch/commits/PR title; `devex check` runs lint then tests (fail-fast). Bypassable with `--no-verify` — re-validated at L3.
3. **PR Pipeline** — full lint, unit + property-based tests, contract validation against `openapi.yaml`, `cdk synth` with FinOps tag enforcement via Aspects (priority `READONLY`), DORA + audit event emission. Required status check on `main`.
4. **Integration Pipeline (designed, deferred)** — promotion across Sandbox → Staging → Prod. Multi-env is already structured (Pattern A: one `Stack` instance per env in `bin/`); the PoC ships the PR pipeline only.

Auditability is a dividend, not an afterthought. Every stage emits one structured JSON event with shared keys (`work_id`, `team`, `repo`, `stage`, `status`, `actor`, `timestamp`, `git_sha`, `framework_version`). The same event stream feeds DORA dashboards and SOC 2 audit — one primitive, two consumers.

Scope of "DORA" today vs at Integration Pipeline activation. The PR-pipeline stages emitted today (`work-id-validation`, `small-tests`, `contract-validation`, `cdk-synth`, `dora-summary` — the last is currently a PR-pipeline summary, not a canonical DORA event) support comparable Python⇌Go metrics: PR Pipeline Failure Rate, PR Cycle Time, Per-Stage Flakiness. **The four canonical DORA metrics** (Deployment Frequency, Lead Time for Changes, MTTR, Change Failure Rate) require `integration-deploy-prod` events, which are gated on the Integration Pipeline (deferred). The schema is shape-correct for both; the emission set today covers the PR-stage subset only. Production-readiness of canonical DORA additionally requires explicit `event_id` (per-emission unique) plus `correlation_key` (derived from `work_id + stage + git_sha`) for exactly-once metric semantics — the current schema supports derivation but doesn't enforce the field.

5. Distribution and contracts

Both products install from Git directly (`uv tool install` for the CLI, `pnpm add github:` for the framework — exact commands in the [README](#)) — no registry overhead, branches and tags work out of the box, internal forks are first-class consumers.

Shared contracts (DORA event, Work ID regex, audit event) live in the monorepo as **mirror modules** — hand-written Zod (TS) and Pydantic (Python), kept in lockstep by contribution rules and a round-trip contract validation job in CI. No code generation: the cost (drift discipline) is lower than the cost of a generator dependency, a build step, and debugging generated code. The mirror model scales with **shared-type count** (currently 2: `DoraEvent`, `AuditEvent`), not with team count — codegen (JSII or equivalent) becomes worth its cost when cardinality exceeds ~15 types or when drift incidents recur >3/quarter, neither of which scale linearly with adoption.

`devex check` reads `testCommand / lintCommands` from `devex.profile.ts` via a small regex parser (with TS-comment stripping). This is intentionally pragmatic for the PoC — robust enough for the file `devex init` produces. Hand-edited profiles fail with mixed loud/silent modes today: imports for field values fall back loudly to a warning +

explicit `--test / --lint` flags (correct); template-string interpolation, block comments inside string literals, and multiple profile exports in one file currently pass through the parser silently (debt — detection of the `${}` interpolation marker is a 3-line fix planned for next iteration). Post-PoC migration target: a `pnpm devex:checks` helper packaged as `npx @devex/framework resolve-profile` that imports `./devex.profile.ts` via `ts-node / tsx` and emits resolved commands as JSON — full TypeScript semantics, no regex layer. Trigger: first defect report from a real consumer where the parser fails silently on a non-typo profile.

6. Plus criteria delivered

Two of the optional challenge "Plus" criteria are shipped — **Kiro steering files** and **Pre-Push Validation** (`devex check`); details in the [README Implementation Status](#). The **Integration Case Study** in [JynLeazy1/transactionify](#) — 5 PRs documenting the adoption journey, latest fully green in CI — operates as live evidence of the shift-left loop the ADR describes.

7. When to reconsider

The architecture has explicit migration triggers, not fixed thresholds:

- **Mirror schemas** → **codegen**. When the shared-type count exceeds ~15, OR drift incidents (PRs that pass R1 review but break the round-trip test post-merge) exceed 3 per quarter, OR mirror-review time per type-change exceeds 20 minutes consistently. None scale with team count; all scale with schema dynamics.
- **devex check regex parser** → **resolve-profile helper**. First real-world defect report on a non-typo profile.
- **GoldenPathTagsAspect mid-aspect renderTags() read** → **Validations.of().addValidation() callback at end-of-synth**. Eliminates dependency on Aspect ordering (third-party `cdk-nag`-style validators or any custom MUTATING aspect at priority 200-999 currently risks bypass). Already documented as latent in the regression test for the false-positive route warnings.
- **devex init ruleset application via custom property** vs current "platform team applies once": triggered when an org reaches ~5 adopting teams and the manual one-time-per-org setup becomes a bottleneck.

Appendix — Reference impact on `transactionify`. Before: 187-line monolithic CDK Stack, no CI/CD, `openapi.yaml` not validated, FinOps tags inline, no structured event emission. After: pure framework adoption reaches 67-line Stack using `PythonLambdaApi` (-64%); current production state with `extraGrants` restoring the upstream `provisioningLambda` is 84 lines (-55%, full upstream feature parity). Generated 5-stage PR pipeline, contract validation enforced, tags fail `cdk synth` if missing, PR-pipeline events emitted per stage, multi-env scaffolding (Sandbox/Staging/Prod) ready. `extraGrants` prop was added mid-adoption via an inner-source PR from the consumer back to the framework — concrete instance of the loop §3 describes. Open roadmap items: Integration Pipeline (prod-deploy events that close the canonical DORA loop), Amazon Q Developer integration, multi-cloud profiles.
